Sample Solved Problem from DSP Proakis

Problem Statement

Given an LTI system with an impulse response $h[n] = (0.8)^n u[n]$, where $u[n]$ is the unit step function, find the system's output when the input is $x[n] = 2 \cos(\pi n/4)$.

Step-by-Step Solution

1. Recognize the System and Input

The system is linear and time-invariant (LTI), characterized by $h[n]$. The input is a cosine sequence.

2. Express the Input in Complex Exponential Form

Using Euler's formula:

$$x[n] = 2 \cos\left(\frac{\pi n}{4}\right) = \operatorname{Re}\{2 e^{j\pi n/4}\}$$

3. Find the System's Frequency Response $H(e^{j\omega})$

The Z-transform of $h[n]$:

$$H(z) = \sum_{n=0}^{\infty} (0.8)^n z^{-n} = \frac{1}{1 - 0.8 z^{-1}}, \quad |z| > 0.8$$

Evaluate on the unit circle $(z = e^{j\omega})$:

$$\backslash$$

$$H(e^{j\omega}) = \frac{1}{1 - 0.8 e^{-j\omega}}$$

$$\backslash$$

4. Compute $\backslash H(e^{j\pi/4}) \backslash$

Substitute $\backslash \omega = \pi/4 \backslash$:

$$\backslash$$

$$H(e^{j\pi/4}) = \frac{1}{1 - 0.8 e^{-j\pi/4}}$$

$$\backslash$$

Calculate numerator and denominator:

$$\backslash$$

$$e^{-j\pi/4} = \cos(\pi/4) - j \sin(\pi/4) = \frac{\sqrt{2}}{2} - j \frac{\sqrt{2}}{2}$$

$$\backslash$$

Thus:

$$\backslash$$

$$1 - 0.8 e^{-j\pi/4} = 1 - 0.8 \left(\frac{\sqrt{2}}{2} - j \frac{\sqrt{2}}{2} \right) = 1 - 0.8 \frac{\sqrt{2}}{2} + j 0.8 \frac{\sqrt{2}}{2}$$

$$\backslash$$

Numerical evaluation:

$$\backslash$$

$$0.8 \frac{\sqrt{2}}{2} \approx 0.8 \times 0.7071 \approx 0.5657$$

$$\backslash$$

So:

\[

\text{Real part}: 1 - 0.5657 = 0.4343

\]

\[

\text{Imaginary part}: 0.5657

\]

Magnitude:

\[

$|D| = \sqrt{(0.4343)^2 + (0.5657)^2} \approx \sqrt{0.1886 + 0.3200} \approx \sqrt{0.5086} \approx 0.713$

\]

Phase:

\[

$\angle D = \arctan \left(\frac{0.5657}{0.4343} \right) \approx \arctan(1.304) \approx 52.5^\circ$

\]

Therefore:

\[

$H(e^{j\pi/4}) = \frac{1}{D} = \frac{1}{|D| e^{j\angle D}} = \frac{1}{0.713 e^{j 52.5^\circ}} = 1.4 e^{-j 52.5^\circ}$

\]

5. Find the System Output in Frequency Domain

The output's frequency component:

\[

$$Y(\omega) = H(e^{j\omega}) X(\omega)$$

\]

Since:

\[

$$X(\omega) = 2\pi \delta\left(\omega - \frac{\pi}{4}\right) + 2\pi \delta\left(\omega + \frac{\pi}{4}\right)$$

\]

The relevant component:

\[

$$Y(\pi/4) = H(e^{j\pi/4}) \times 2$$

\]

Similarly, the negative frequency component:

\[

$$Y(-\pi/4) = H(e^{-j\pi/4}) \times 2$$

\]

But because the input is real, the output is the sum of these conjugate components.

6. Final Time-Domain Output

The output is:

\[

$$y[n] = \operatorname{Re} \left\{ 2 H(e^{j\pi/4}) e^{j\pi n/4} \right\}$$

\\

Using the calculated $|H(e^{j\pi/4})|$:

\\

$$|H| = 1.4, \quad \angle H = -52.5^\circ$$

\\

Thus:

\\

$$y[n] = 2 \times 1.4 \times \cos \left(\frac{\pi n}{4} - 52.5^\circ \right) \approx 2.8 \times \cos \left(\frac{\pi n}{4} - 52.5^\circ \right)$$

\\

This structured methodology not only facilitates learning but also embodies best practices for tackling complex engineering problems.

Analyzing a Typical DSP Proakis Solved Problem: Case Study

To illustrate, let's analyze a representative problem often encountered in Proakis' texts: Designing a Bandpass Filter Using the Fourier Transform.

Problem Overview:

Given a discrete-time signal with a specific spectral content, design a bandpass filter that isolates a

frequency band of interest. Calculate the filter's frequency response and verify its effectiveness through simulation.

Step 1: Understanding the Signal and System Requirements

- Signal characteristics: For example, a sampled signal containing components at 500 Hz and 1500 Hz.
- Sampling frequency: 4000 Hz.
- Objective: Filter out the 1500 Hz component, retaining the 500 Hz frequency.

Step 2: Determine Filter Specifications

- Passband: 450 Hz to 550 Hz.
- Stopband: Frequencies outside this range.
- Transition band: Defined based on practical constraints.
- Filter type: Finite Impulse Response (FIR) or Infinite Impulse Response (IIR).

Step 3: Selecting Filter Design Method

Proakis discusses several methods?windowing, Parks-McClellan algorithm, etc. For simplicity, assume the use of the windowing method:

- Choose an ideal bandpass filter's impulse response.
- Apply a window function (e.g., Hamming, Hann) to obtain a realizable FIR filter.

Step 4: Calculating Filter Coefficients

- Compute ideal impulse response $\{h_d[n]\}$ via inverse Fourier transform.
- Apply window $\{w[n]\}$: $h[n] = h_d[n] \times w[n]$.

Step 5: Analyzing Frequency Response

- Use the Discrete Fourier Transform (DFT) or the Fast Fourier Transform (FFT) to evaluate the filter's frequency response $\{H(e^{j\omega})\}$.
- Verify that the passband is adequately preserved and the stopband attenuation meets specifications.

Step 6: Simulating and Validating

- Generate a test signal containing multiple frequency components.
- Pass it through the designed filter.
- Analyze the output to confirm suppression of unwanted frequencies.

Final Remarks:

This problem encapsulates core DSP concepts: filter design, Fourier analysis, system response, and simulation. It demonstrates how theoretical principles translate into practical filter implementation.

Key Concepts and Techniques Demonstrated in the Solved Problem

The above case study illustrates several essential DSP techniques:

- Fourier Transform and Spectral Analysis: Understanding how signals and filters behave in the frequency domain.
- Filter Design Principles: Translating specifications into filter coefficients through algorithms like windowing.
- Sampling Theorem: Ensuring the sampling rate accommodates the highest frequency component to prevent aliasing.
- Windowing Method: Managing the trade-off between filter length, transition width, and ripple.

These concepts form the backbone of many DSP applications, from audio processing to communications systems.

Interpreting the Results and Practical Implications

The success of the filter design hinges on meeting the specifications?selecting appropriate window functions, filter lengths, and verifying the spectral response. Practical considerations include:

- Computational Efficiency: Longer filters improve selectivity but increase computational load.
- Real-time Constraints: Implementing filters within hardware with limited processing power.
- Robustness: Ensuring stability and minimal distortion over varying operating conditions.

A well-executed DSP problem solution exemplifies the iterative nature of engineering design?balancing ideal performance with real-world constraints.

Broader Perspectives: Learning from Proakis' Approach

Proakis' problems emphasize a thorough understanding of DSP fundamentals paired with analytical rigor. This approach fosters:

- Critical Thinking: Encouraging students to question assumptions and explore alternative solutions.
- Mathematical Rigor: Reinforcing the importance of precise calculations and reasoning.
- Application-Oriented Learning: Connecting theoretical insights with industry-relevant problems.

Moreover, the solved problems serve as templates for tackling complex, multi-step challenges in advanced DSP applications.
