Stages of Photosynthesis

Photosynthesis occurs in two main stages: light-dependent reactions and light-independent reactions (Calvin cycle).

1. Light-Dependent Reactions

These reactions occur in the thylakoid membranes of the chloroplasts and require light to take place.

- **Purpose:** Convert light energy into chemical energy (ATP and NADPH).
- **Key Steps:**
 - Absorption of light by chlorophyll pigments.
 - Excitation of electrons to a higher energy state.
 - Splitting of water molecules (photolysis) to release oxygen, protons, and electrons.
 - Electron transport chain transfers electrons, leading to ATP synthesis via chemiosmosis.
 - Formation of NADPH from NADP⁺ and electrons.

2. Light-Independent Reactions (Calvin Cycle)

These reactions take place in the stroma of the chloroplast and do not require light directly.

- **Purpose:** Use ATP and NADPH to synthesize glucose from carbon dioxide.
- **Main Steps:**
 - Carbon fixation: CO₂ combines with RuBP (ribulose biphosphate) catalyzed by the enzyme Rubisco.
 - Reduction: The 3-phosphoglycerate molecules are converted into glyceraldehyde-3-phosphate (G3P) using ATP and NADPH.
